

## **Exercise 11 – Web Technologies & Provisioning**

### **Automated provisioning using Terraform**

The goal of this exercise is to create a Terraform configuration that automatically sets up multiple servers and connects them together.

Before starting this exercise make sure you have Terraform and Docker installed and running on your system.

Create a Terraform configuration file that will automatically provision the following setup in Docker:

**Figure 1:** diagram

Use the provided Flask application. Once the system is running, you should see four containers in

Docker. When accessing `http://localhost:3000`, the response should alternate between:

- Connected to PostgreSQL | Using Flask1
- Connected to PostgreSQL | Using Flask2

indicating that traffic is being load-balanced between the two Flask applications.
